===

The problem in current Word2Vec and other embedding methods is that they are slow to train and after that they don't have artistic accuracy.

This problem can be solved by the **SILS Architectural framework**. Which stands for **Static Intent Logic Seed**.

I have authored a library for that called: **LIBSILS.C++**

It is not a new framework, instead it is an optimization, a fix on top of an architecture called Word2Vec CBOW.

Here the Word2Vec model finds and assigns words like:

"The cat sat on the mat." the library tries all the predictions on the Layer 0.

Example: "The cat _ on the mat." and like so.

But then the **libsils** improve them by removing all the useless words on the layer 1, by adding nearest **NOUNS** and **VERBS**. Which provides a very high increment on story generation and text generators.

The model will put **"SAT"** (VERB) on the word **"cat"** (NOUN) telling the capability of the NOUN. And in the story generation context.

The model will be able to generate that **"Cat sat** down on the bed."
And in context can be used that: *"The king lived with the queen"*.

According to myself, and all models by **Algoritms-AI** use this scema and you can even use it.

Layer 0 → Contains the Word2Vec (nearest words)

Layer 1 → Contains the SILS NOUN (nearest characters and places)

Layer 2 → Contains the SILS VERB (nearest capabilities and works)
